Tapered roller bearings

SNR

Tapered roller bearings

Definition and capabilities

➜ Definition

Tapered roller bearings with a single row of rollers are always mounted opposing another bearing of the same type to provide rigid assemblies, particularly when preloaded.

■ Cages

Tapered roller bearings are usually equipped with a pressed steel cage. In some cases with a synthetic material cage.

■ Contact angle

The rings of this bearing are detachable: the outer ring (cup) is not joined to the rest of the bearing which is made up of the inner ring (cone) and rollers held on the cone by the cage. A tapered roller bearing can accept axial loads in one direction only. It must be mounted in opposition with a bearing of the same type.

ISO 355 Standard defines the different series of tapered roller bearings with contact angles of 10 to 30°. For a given radial load, the greater the angle of the cup, the greater the axial load that the bearing can withstand. SNR has adopted designations in accordance with this standard for the new "intermediate" series and has kept the former designations for the other series.
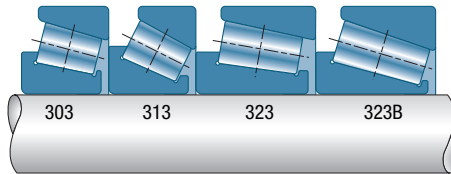

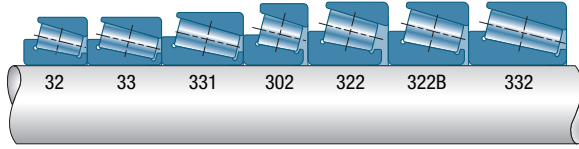

➜ Capabilities

■ Loads and speeds

The tapered roller bearing is an angular contact bearing that can withstand high radial and axial loads.

■ Misalignment

The shape of the contacting profiles allows misalignment in the range of 0.06°.

Series

# Variants

■ **Special chamfer**

Special chamfer on the large face of the cone to adapt to the large fillet radius of the shoulders of shafts such as those of wheel axles.

■ **Flange on cup**

■ **Matched bearings**

They are made up of two bearings and usually two spacers to form a single assembly. The elements of a given matched assembly cannot be exchanged with those of another assembly.

SNR
Tapered roller bearings *(continued)*

Tolerances and clearance

→ Tolerances

These bearings are supplied in standard precision with tolerances in accordance with ISO 492 Standard. They can be supplied on request with specific tolerances on one or more dimensions or characteristics.

→ Clearances

■ Axial clearance

As these bearings are always mounted in opposition, the axial clearance is determined by the adjustment of the bearings at installation. That is to say by the adjustment of the relative initial position of the cones with respect to the cups. The adjustment determines a mechanical clearance (positive clearance) or a pre-load (negative clearance).

■ Types of assembly

Face-to-face assembly (O)

This arrangement is to be used in applications involving temperature variations, or when the points of load application of the two bearings need to be as far apart as possible. It more specifically enables the creation of compact assemblies with either pre-loading or clearance.

The adjustment is made on the distance di between the cones of the two bearings which is determined by either a spacer length or an adjustment nut.
Back-to-back assembly (X)

To install a shaft fully equipped with the bearings in a housing.

The adjustment is made on the distance De between the cups of the two bearings, and is determined by shims or an adjustment nut.
■ Relation between the axial clearance J_a and the radial clearance J_r of a bearing

$$J_a = 1.25\ Y \cdot J_r$$

■ Pre-load

Tapered roller bearings are preloaded whenever one wants to ensure the axial stiffness of the assembly (bevel gear bearings. machine-tool spindle bearings. etc.). The nominal value of the pre-load is fixed for each application according to the loading conditions and the characteristics of the chosen bearings.

Consult SNR for the preparation of a preloaded bearing file.

SNR establishes two characteristic curves for each bearing reference:

• The axial penetration curve that characterises the bearing stiffness which depends on the contact angle, the number of rollers, and their effective length.
• The friction torque curve which enables to check that the pre-loading adjustment is correct using a torque gauge

■ Axial clearance on assembly for two separate bearings

As these bearings are always mounted in opposition. their internal clearance is determined by the adjustment on assembly that determines the axial clearance of the shaft.

For information. the relation between the axial clearance and the corresponding radial clearance is given by the formula:

$$J_r = 0{,}8\ /\ Y \cdot J_a \quad (Y = 0.4\ \mathrm{cotg}\alpha)$$

These bearings can be mounted with a pre-load if necessary to secure an axial stiffness of an assembly. The maximum speed in this case is reduced and depends on the pre-load value.

Consult SNR.

Tapered roller bearings *(continued)*

Design criteria

■ **Bearing life**

■ **Shaft mounted on two single bearings**

Equivalent dynamic load

The axial balance of the shaft depends not only on the forces applied, but also on the forces induced by the radial loads applied on each bearing.

Equivalent static load

Its value Po is the greater of the two values obtained using the following formula:

$$P_0 = F_r$$
$$P_0 = 0.5\, F_r + Y_0 \cdot F_a$$

■ **Shaft with one of its two assemblies made up by two matched non-preloaded bearings assembled in an O or X arrangement**

O assembly
X assembly

This assembly is considered as a single double-row roller bearing which centre O is the mid-point of the distance AB between the load application points. The assembly of a shaft with this type of assembly is hyperstatic (3 seating points: A. B. C) and can only be likened approximately to an arrangement of two assemblies if the distance AB is less than L/5 and the stiffness of the assembly is satisfactory (misalignment < 0.06°). In all other cases, consult SNR.

Equivalent dynamic load of the double pillow block (ISO 281 Standard)

$$P = F_r + 1.1\ Y.\ F_a \qquad \text{if} \quad F_a / F_r \leq e$$

$$P = 0.67\ F_r + 1.68\ Y.\ F_a \quad \text{if} \quad F_a / F_r > e$$

Basic dynamic capacity of the double bearing

The basic dynamic capacity of an assembly of two identical bearings is:

$$C_e = 1.715\ C$$

Equivalent static capacity of the double pillow block

$$P_0 = F_r + 1.1\ Y\ .\ F_a$$

Basic static capacity of the double pillow block

The static capacity of the assembly of two identical bearings is twice that of a single bearing.

$$C_{0e} = 2\ C_0$$

■ **Calculation of preloaded bearings**

The values of the induced forces involved in the axial equilibrium of two bearings depend on the applied pre-load and the bearing stiffness characteristics. Consequently, the calculation of the equivalent load on each bearing is complex and must be performed by the SNR Technical Service.

SNR

Tapered roller bearings *(continued)*

Installation/assembly criteria

■ **Interchangeability of elements of the same reference**

As the cones and cups of tapered roller bearings are separable, ISO has established:.
• the nominal dimensions of the small diameter of the cup raceway (E)
• the contact angle (α)

Interchangeability of SNR elements
The cones and cups of the same reference are totally interchangeable. with the total width of the bearing (dimension T) remaining within the standard tolerances (ISO 492).

Interchangeability of an SNR element with an element of another make

Interchangeability is possible if the non-SNR elements comply with ISO 355 Standard, particularly dimensions α and E. However, as the tolerances on these dimensions, the raceway profile shapes, the quality of steel and the surface conditions are specific to each manufacturer. The performance of such assemblies risks can be significantly reduced. Such assemblies should therefore be avoided.

Some SNR references in old designs are not interchangeable with other makes. They are identified in the "List of Standard Bearings".

■ **Adjustment parameters**

The assembly of standard bearings always requires an adjustment due to the fact that their elements can be separated.

The adjustment depends on the assembly dimensions and their tolerances, which are:

The functional dimensions of the bearing
• Bore d
• Outer diameter D
• The distance between the cone and cup faces of a given bearing: dimension T

The functional dimensions of the assembly
• The distance between the cup shoulders (De)
• The distance between the cone shoulders (di)
• The diameters of the shaft and housing seating surfaces

The generally accepted tolerance for a given clearance (positive or negative) makes it necessary to repeat the adjustment operation for each assembly, taking in consideration amplitude of standard bearing tolerances and the assembly dimensions.

One then adjusts one of the shoulder distances (De) or (di) at each operation to compensate for the variations in the other dimensions of the assembly.

Adjustment is a relatively long and repetitive operation that has to be performed by specialised personnel capable of ensuring its precision and reliability.
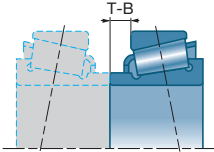

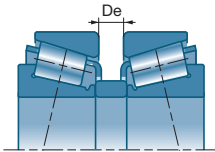

■ Installation without adjustment

In many high volume production assembly operations, the dimensional tolerances have a reduced normal statistical distribution. In such cases, by using bearings which also have reduced tolerances, mountings will have a 99.73% probability that no further adjustment will be required, which is suitable for most applications.
Main applications: vehicle wheels and gear boxes.
The bearings are usually fitted close to each other in an O arrangement.

■ The two possibilities of adjustment-free assembly are:

Type of assembly	Pre-adjusted bearings	Matched assembly
Adjustment schematic		
Bearing characteristics	◗ Reduced tolerance on the position of the cone with respect to the large face of the cup (dimension T - B). ◗ Interchangeable cone and cup. ◗ Cone usually extended to avoid the need for a spacer.	◗ Set of two pre-adjusted bearings with a reduced tolerance on the distance of the 2 cups (0.03 mm approximately.). ◗ Elements not interchangeable with those of another assembly.
Assembly characteristics	◗ Assembly of large series in O arrangement. ◗ Tolerance of about 0.05 mm max. on the distance (De) of the cup shoulders.	◗ Assembly of large or medium series. ◗ Tolerance of about 0.05 mm max. on the distance (De) of the cup shoulders.
Axial clearance tolerances	◗ Tolerance of the order of 0.15 / 0.20 mm with a probability of 99.7%. The clearances outside this probability (0.3%) lie within a theoretical range of 0.4 to 0.6 mm approx.	◗ Tolerance of the order of 0.10 / 0.15 mm with a probability of 99.7%. The clearances outside this probability (0.3 %) lie within a theoretical range of 0.25 to 0.4 mm approx.

Prefixes and suffixes

■ Prefixes

R	Special chamfer on the large face of the inner ring (cone)

■ Suffixes

B	Suffix for series 322 and 323 with increased angle
A. C	Internal design indices
T	Flange on outer ring (cup)
P6X	Bearing whose tolerance on dimension T complies with precision class 6X
